

Is a lower RX value for optical modules always better

Overview

RX Sensitivity is the minimum optical power the receiver needs to correctly interpret a signal, expressed in dBm. Better (lower) RX sensitivity means you can tolerate weaker signals and longer fiber spans, but it also makes the system more susceptible to noise if the link is poorly. Minimum Receiver Power (sometimes referred to as Receiver Minimum Input Power) is the lowest level of optical power at which the module is guaranteed to operate without exceeding a specified bit error rate (typically $BER \leq 10^{-12}$). This value is typically used in optical link budgeting to ensure. The key to a reliable connection is understanding three core metrics that SFP modules expose: transmit (TX) power, receive (RX) sensitivity, and the resulting optical budget.

Use optical attenuators to prevent damage. In multi-mode fiber, especially with 850nm optics (like SX modules), TX power typically ranges from -9 to -3 dBm, and RX can receive down to ...

The RX receiving sensitivity represents the lowest optical signal intensity that the optical module can receive at the normal allowable bit error rate. Once the optical signal falls below the ...

When the RX sensitivity of an optical transceiver is found to be around -12 dBm or lower, it generally signals a problem with the cable infrastructure. The issue could be a result of a bad splice, ...

A lower BER indicates a more reliable system with fewer transmission errors, which is essential for maintaining data integrity. Achieving an optimal BER involves ensuring that both the Tx ...

The lower the RX sensitivity, the better the module can detect weaker signals. Both TX and RX power are fundamental to maintaining signal integrity and ensuring reliable communication.

Some MMF setups use 1300nm optics, offering TX levels of -5 to -1 dBm and RX ranges down to -14 dBm, supporting distances up to 2 kilometers. Tip: Always clean your fiber connectors.
