

Temperature and humidity requirements for optical module devices

Overview

Standard storage conditions for optical transceivers require controlled temperature, non-condensing humidity, and strict electrostatic discharge protection in accordance with Telcordia GR-468-CORE. Managing heat is a crucial part of the Opto-mechanical design process to keep the device functioning within spec and to maintain image quality. When the operating temperature of an optical module exceeds its design range, it will not only affect its performance, but may also cause serious problems such as. This guide describes the general handling measures and precautions when handling optical transceivers to ensure they can be handled with reduced risk for damage. Maintaining these environmental tolerances prevents micro-condensation and substrate degradation, directly reducing. Optical modules can be categorized into commercial temperature, extended temperature and industrial temperature grades based on their operating temperature ranges, as shown below: Table 1: Operating Temperature Ranges of Optical Modules Users can select modules with different temperature grades. A PIC and a

standard platform-agnostic DSP typically operate with signals of differing intensities, so they need some RF analog electronic components to “talk” to each other. This signal power conversion overhead constitutes roughly 2-3 Watts or about 10-15% of transceiver power consumption.
