### Overview

Testing Ethernet switch chips is a complex process involving multiple stages: functional testing, performance testing, scalability testing, power consumption testing, reliability and stability testing, security testing, interoperability testing, and compliance testing. It's not just about checking if a link light is green - it's about verifying the logic behind the connection. Ensure that only affected switches show change in and access switches. They should not be affected. Network switch stress testing involves subjecting a switch to high traffic volumes and data loads to evaluate its resilience, throughput, and overall performance under demanding conditions. Since time-critical storage operations are offloaded to the SmartNIC, it must be able to perform despite being impacted by various network impairments such as varying latency and jitter.
